## **NANOSTRUCTURED CNT-MnO<sub>2</sub> ELECTRODE PREPARED BY ELECTROPHORETIC DEPOSITION METHOD FOR SUPERCAPACITORS**

**RINGKASAN:** Komposit Nanotub Karbon (CNTs)-manganese dioksida (MnO<sub>2</sub>) telah disediakan sebagai elektrod positif untuk kapasitor lampau melalui kaedah Pemendapan Elektroporetik (EPD). Komposit elektrod tersebut mempamerkan kelakuan kapasitan-pseudo melalui tindakbalas elektrokimia antara MnO<sub>2</sub> dan ion OH untuk menghasilkan MnOOH di dalam elektrolit KOH. Nilai kapasitan spesifik yang dicapai adalah dalam julat 60-210 F/gm, melalui analisa kitaran volumetri dengan kadar imbasan 5 hingga 100 mV/s bergantung kepada jisim dan komposisi elektrod.

**ABSTRACT:** Carbon nanotubes (CNTs)-manganese dioxide (MnO<sub>2</sub>) composite as positive electrode for supercapacitor has been prepared by Electrophoretic Deposition (EPD). The composite electrodes exhibited pseudocapacitance reactions in a 6 M KOH electrolyte resulting from the reaction of MnO<sub>2</sub> with OH ions to form MnOOH. Specific capacitance values ranging from 60-210 F/g were obtained by means of cyclic voltammetry scanning within a scan rate of 5 mV/s to 100 mV/s from electrodes of different mass and composition.

## **INTRODUCTION**

MnO<sub>2</sub> has been considered as a promising electrode material for electrochemical supercapacitors because of its low cost and excellent capacitive performance. Many types of manganese dioxides have been investigated including crystalline and amorphous phase. However, MnO<sub>2</sub>, exhibited low specific capacitance, because of high resistivity of bulk manganese oxide. One way of overcoming this is by adding the conductive materials such as carbon (Malak-Polaczyk *et al.*, 2010; Zhao *et al.*, 2014), carbon nanotubes (Wang *et al.*, 2013; Wang *et al.*, 2012; Li *et al.*, 2013; Wang *et al.*, 2011; Yang *et al.*, 2012; Sivakkumar *et al.*, 2007; Zou *et al.*, 2011; Teng, Santhanagopalan & Meng 2010; Teng, Santhanagopalan, Wang, *et al.*, 2010), graphene (Deng *et al.*, 2013;

Wu & Fu 2013; Yang *et al.*, 2014; Lim *et al.*, 2014; Jafta *et al.*, 2013; Tang *et al.*, 2014) and polymers (Yan *et al.*, 2014; Yoon & Kim 2013) to form a composite.

Concerning the materials issues, MnO<sub>2</sub> is one of the most studied materials as a low-cost alternative to RuO<sub>2</sub>. It has a very high theoretical capacitance of ~1380 F/g but suffers from poor conductivity, hence lower than 30 % of the value was obtained. To further improve the performance of MnO<sub>2</sub>-based supercapacitor, it is necessary to design MnO<sub>2</sub> materials into nanoarchitectures with desirable physicochemical features or composites with other materials, such as carbon derivatives or conductive polymer (Lei *et al.*, 2012; Li *et al.*, 2012; Sen *et al.*, 2013).

Composites of CNT-MnO<sub>2</sub> also have been investigated by various researchers for improving the performance of the composite electrode (Wang *et al.*, 2012; Li *et al.*, 2012). Generally, it has been found that by introducing CNTs into the matrix composite improves the electrochemical performance of the MnO<sub>2</sub> by lowering the electrical resistivity of the electrode. The conventional method for fabricating electrode from CNTs or metal oxides or the composite of both is by a paste coating method. In this method, the active material is mixed together with a certain amount of binder and acetylene black to form a paste before coating. Binder is used to improve adhesion between the particles and the substrate; while acetylene black is added to improve electrical conductivity (Kiamahalleh *et al.*, 2010; Cottineau *et al.*, 2006; Hassan *et al.*, 2014; Pandolfo *et al.*, 2006). However, these two materials lacked capacitive properties; hence can be considered 'dead weight'; which effectively reducing the specific capacitance of the electrode. To alleviate this, we propose a method to produce electrode material without usage of binder and acetylene black. The method is known as an electrophoretic deposition (EPD). Various researchers have applied this method to produce CNTs coating on various substrate for different applications. The CNTs are first charged with positive manganese ions (Mn<sup>2+</sup>), whereby during the deposition process the CNTs and manganese oxide are being deposited electrophoretically. This simultaneous reaction of the electrophoretic and electrochemical deposition of CNTs and manganese oxide/hydroxides is the novelty of this study.

## MATERIALS AND METHODS

The carbon nanotubes in this study was supplied by Shenzen Nanoport (NTP), China. The properties are shown in the Table 1.

**Table 1.** Properties of the supplied CNTs

Diameter	20-50 nm
Length	5 microns
Purity	At least 95%
Synthesis Method	CVD

10 gm of the CNTs was refluxed with concentrated nitric acid for 8 hrs. The nanotubes were then repeatedly washed with distilled water and filtered, followed by drying at 80° C for 24 hours. This process apart from purifying the CNTs, would functionalize the CNTs with carboxylic groups (-COOH). During refluxing process, the oxygen-containing groups are introduced to the ends and sidewalls of the tubes. These groups, which are chemically attached to the tubes, are mostly represented by -COOH groups, less by -C=O, and -OH groups (Datsyuk *et al.*, 2008; Yang *et al.*, 2007). 5 mg of the refluxed CNTs were then dispersed ultrasonically in 100 ml ethanol, by ultrasonic equipment (VCX 500, Sonics USA) with 50 % amplitude for 2 hours. In order to charge the carbon nanotubes, three different concentrations of Mn(NO<sub>3</sub>)<sub>2</sub>.6H<sub>2</sub>O were added into the suspension at different concentrations of  $1.0 \times 10^{-5}$  mol/l,  $5.5 \times 10^{-5}$  mol/l and  $1 \times 10^{-4}$  mol/l, respectively. Nickel foils with the size of 3 x 5 cm were used as electrophoretic deposition (EPD) electrodes, and were put in parallel at 2 cm distance facing each other into the suspension.

An electric field of 100 V was applied across the two electrodes using high voltage DC power supply (KENWOOD Regulated DC power supply, model PD110-5AD). The deposition duration was 5 minutes for each charger salt concentration. The weight of the substrate before and after deposition were measured and recorded. The microstructure of the CNTs coated electrodes were investigated by high resolution Scanning Electron Microscopy (LEO 1525). Transmission Electron Microscope (TEM) analysis was performed on TECHNAI Phillips equipment. Effects of different concentration of charger salt on the chemical composition of CNT films were analysed by EDX. The XPS data collection was also performed on the coated samples using Omicron XPS system. The analysis of the XPS results was performed using CASA software. The cyclic voltammetry tests were performed using Autolab PGSTAT 30 system utilizing Ag/AgCl and platinum foil as a reference and counter electrode respectively.

## RESULTS AND DISCUSSION

SEM observation on the coated surface revealed the deposition of the CNTs on the nickel substrate. The CNTs were observed to cover the entire nickel surface without recess or voids. The typical representation of uniform coatings was observed from coatings deposited of -the suspensions containing the charger salt within concentration range of  $1 \times 10^{-5}$  to  $1 \times 10^{-4}$  mol/l. It can be observed from Figure 1 that the coatings produced have a nanoporous structure because of the entanglement of the CNTs among each other. This is highly desirable as the porous electrode would provide clear pathways for ions diffusion into the electrode, hence, better materials utilization. TEM images in Figure 2 exhibits the formation of MnO<sub>2</sub> nanoparticles attached to the surface of the CNTs particles

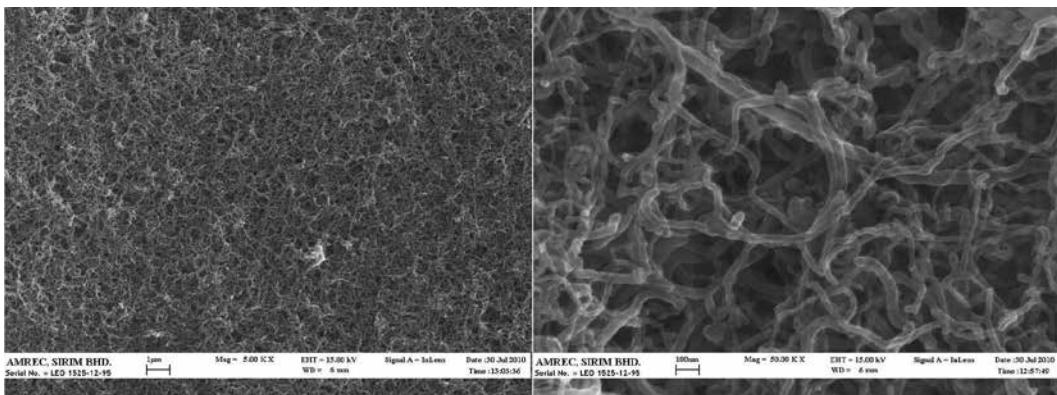

Figure 1. Surface morphology of CNTs-MnO<sub>2</sub> electrode at (a) 5 K magnification and (b) 50K magnification

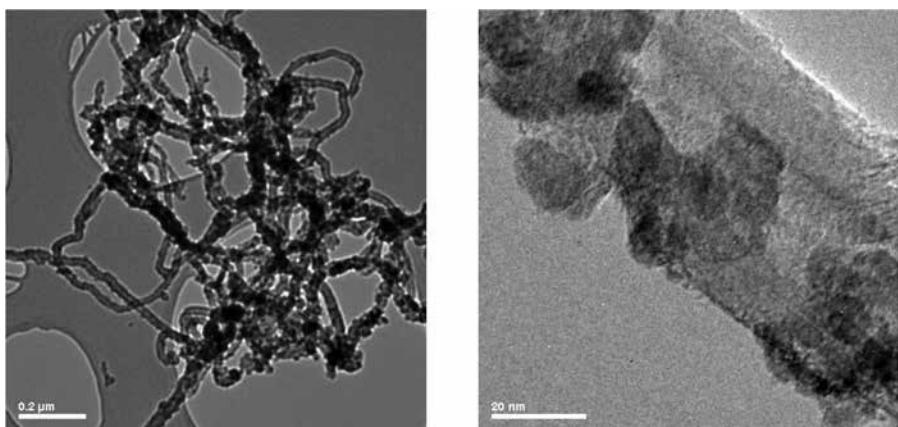

Figure 2. TEM images of CNT-MnO<sub>2</sub> composite electrode showing MnO<sub>2</sub> nanoparticles on (left) CNTs bundles and (right) individual CNT

It can also be seen that higher concentration of charger salt in the suspension always produced a coating with higher weight. The weight of the coating of 0.3, 0.5 and 0.7 mg/cm<sup>2</sup> was obtained for the deposition from CNTs suspension containing charger salt concentration of  $1 \times 10^{-5}$ ,  $5.5 \times 10^{-5}$  and  $1 \times 10^{-4}$  mol/l respectively. EDS analyses performed on the deposited samples, as shown in Figure 3 revealed elemental presence of C, Mn and O respectively. It was also found that at the charger salt concentration of  $1 \times 10^{-5}$  mol/l, the numbers of Mn atoms detected were only 6 per 100 C atoms. This value increases to 24 per 100 C atoms for coating deposited from  $5.5 \times 10^{-5}$  mol/l charger salt containing bath, and subsequently, for coating deposited from  $1 \times 10^{-4}$  mol/l charger salt containing bath, gave the highest count of Mn atoms of about 46 per 100 C atoms. This was translated to weight percentage of approximately 12 %, 45 % and 67 % of MnO<sub>2</sub> in the CNTs-MnO<sub>2</sub> composite coating respectively.

Elemental mapping of Mn, C and O showed uniform distribution of respective element on the electrode surface, as shown in Figure 4, indicated by the presence of Mn and O elements together with the C element, suggesting the uniform distribution of MnO<sub>2</sub> on the surface of carbon nanotubes.

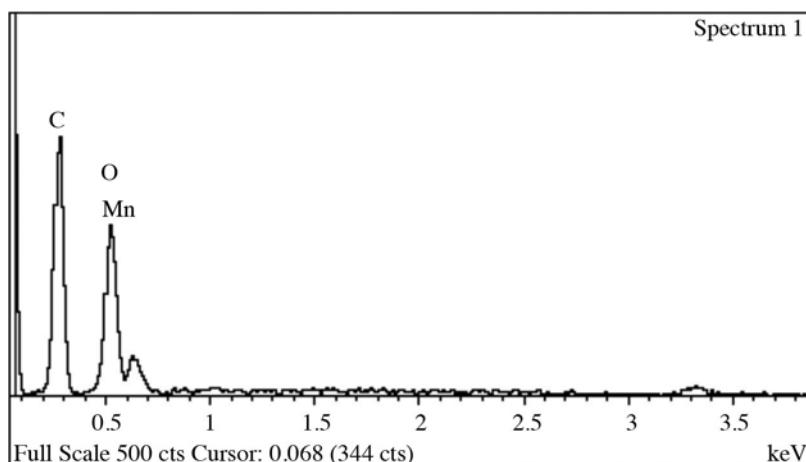

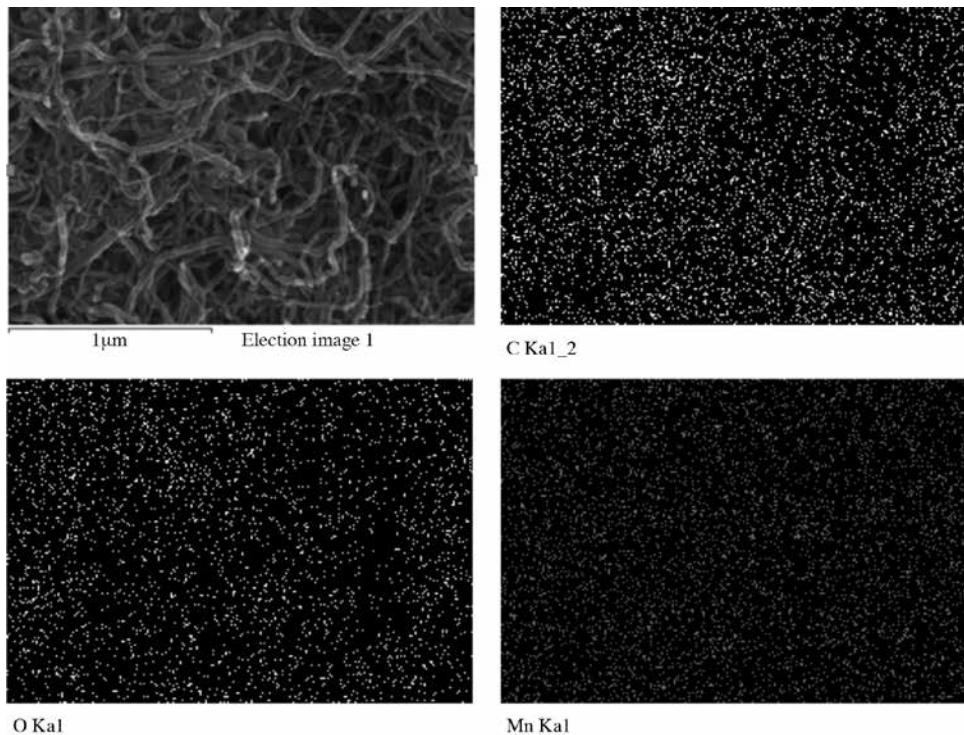

Figure 3. EDS spectra of CNTs-MnO<sub>2</sub> electrode

*Figure 4.* EDS mapping showing elemental distribution of C, O and Mn

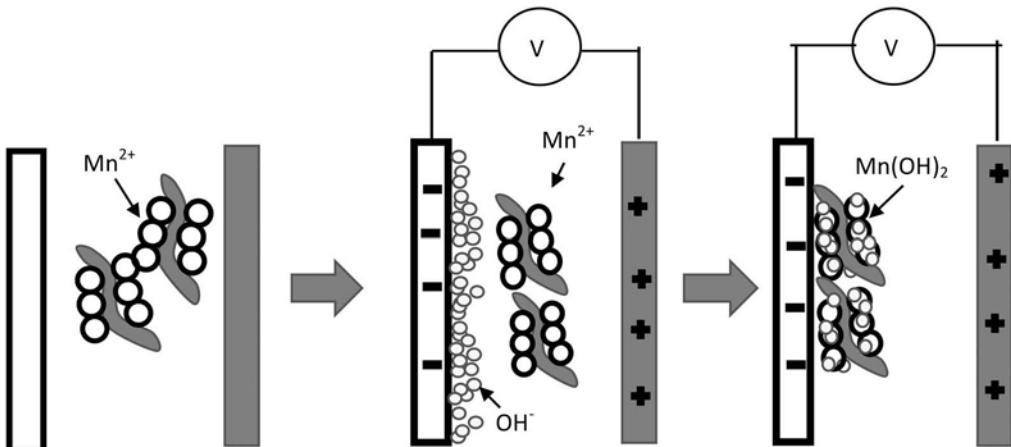

XPS analysis by curve fitting on Mn 2p<sup>3/2</sup> peak as shown in Figure 6(a) revealed the existence of two peaks at 641.9 eV and 644.2 eV respectively. Peak at 641.9 eV is related to the MnO<sub>2</sub>, while binding energy of 644.2eV and 657.5 can be attributed to existence of unconverted Mn(OH)<sub>2</sub>. Deconvolution of O region, shown in Figure 6(b), yielded three O related components. Binding energy at 529.6 eV relates to MnO<sub>2</sub> and higher values of 531.1 and 532.8 eV corresponds to the binding energies of OH (manganese hydroxides) and H-O-H (adsorbed water) respectively (Pang *et al.*, 2000). During the application of voltage across the electrodes in electrophoretic process; these reactions took place at the cathode surface:

Mn(OH)<sub>2</sub> would be deposited simultaneously with the CNTs to form a composite coating on the cathodic substrate. However, Mn(OH)<sub>2</sub> is unstable in the air, and upon contact with the air, it will turn into manganese dioxide through the following reaction (Liu *et al.*, 2009; Tomandl *et al.*, 2004)

The mechanism for the deposition of CNTs-MnO<sub>2</sub> composite material can be depicted in Figure 5 below.

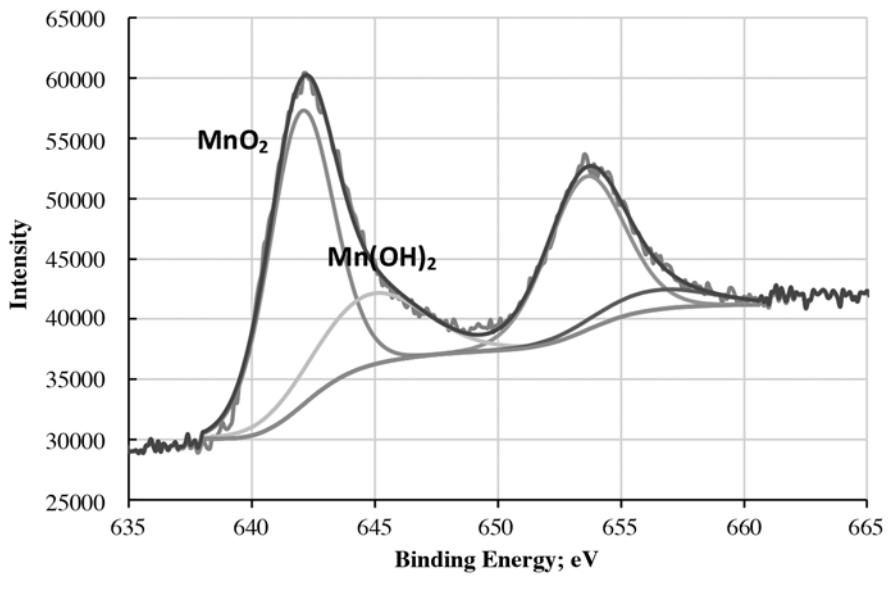

The Mn<sup>2+</sup> charged nanotubes is dispersed in a suspension

Upon application of suitable potential across the electrodes; the charged nanotube is attracted to the negative electrode. At the same time OH<sup>-</sup> ion is generated at the negative electrode.

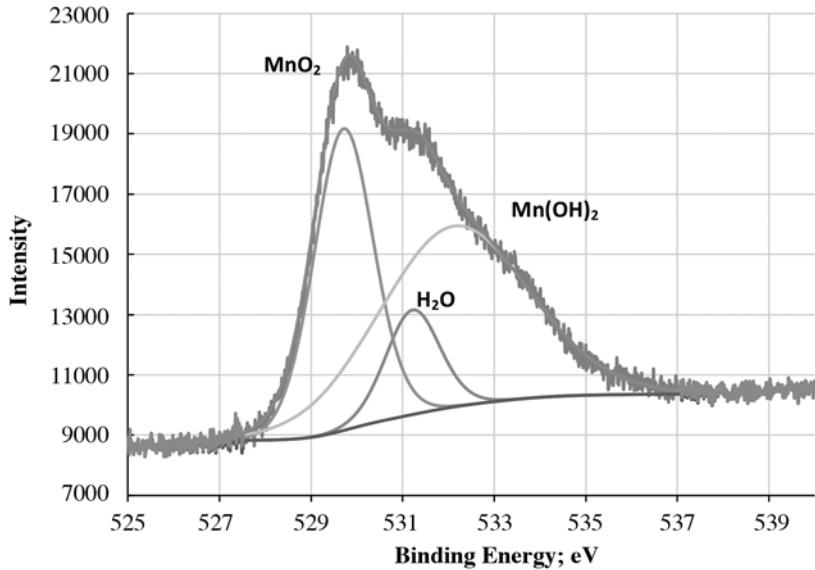

OH<sup>-</sup> ions react with Mn<sup>2+</sup> ions to form Mn(OH)<sub>2</sub> molecules. The CNTs-Ni(OH)<sub>2</sub> material is formed on the negative electrode surface

*Figure 5. Schematic diagram of deposition mechanism of CNTs-Mn(OH)<sub>2</sub> by electrophoretic deposition process*

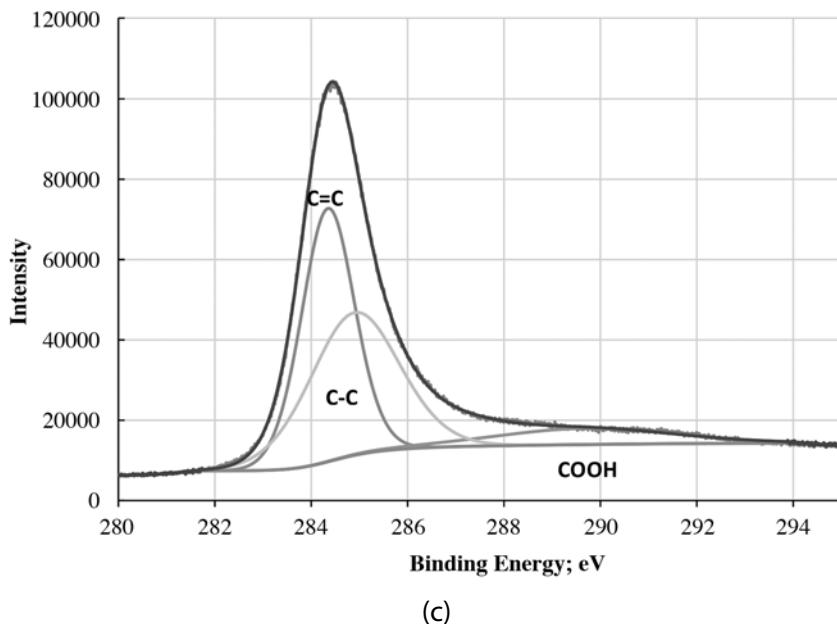

In Figure 6(c), it can be seen that the dominant carbon peak is observed at 284.9 eV of C=C(sp<sup>2</sup>) binding energy, related to the carbon structure in the CNTs, C-C. Binding energy at 285.5 is assigned to sp<sup>3</sup> or C-C bonding and binding energy of 289.5 eV is for -COOH (Okpalugo *et al.*, 2005). The COOH bonding at binding energy of 288.3 eV is related to CNT functionalization occurring during refluxing process. The refluxing process would functionalize the CNTs with carboxylic groups (-COOH). During refluxing process, the oxygen-containing groups are introduced to the ends and sidewalls of the tubes. These groups, which are chemically attached to the tubes, are mostly represented by -COOH groups, less by -C=O, and -OH groups (Datsyuk *et al.*, 2008; Yang *et al.*, 2007).

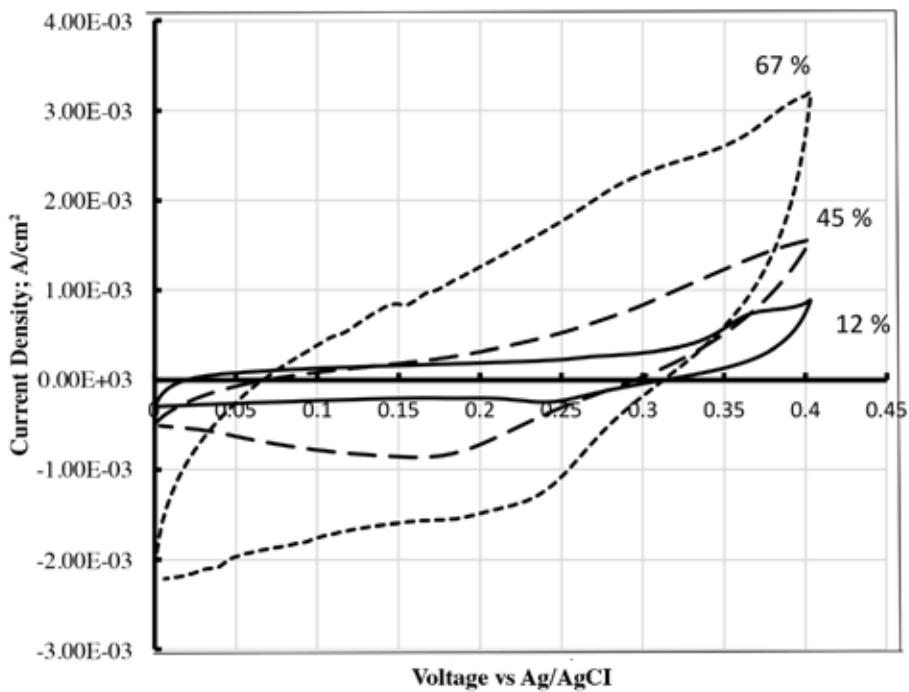

**Figure 6.** Deconvolution of elemental components in XPS analysis; (a) Mn (b) O and (c) C

The electrochemical reaction of MnO<sub>2</sub> in KOH solution is described below (Wang *et al.*, 2015; Deng *et al.*, 2011):

It was observed that the charge accumulation was greater in electrodes with higher mass loading with higher MnO<sub>2</sub> concentration, as shown in Figure 6. The electrode of 67 % MnO<sub>2</sub> shows the highest charge storage capacity followed by 45 % and 12 % respectively. Higher storage capacity of the 67 % electrode is due to the higher mass loading and MnO<sub>2</sub> content of the electrode; which effectively increase the availability of the active material to store charge through redox reactions.

*Figure 7. Cyclic voltammetry profile of the electrodes of different mass and composition*

From the graph of specific capacitance Figure 7, it can be seen that the highest specific capacitance value of 210 F/gm was obtained at the scan rate of 5 mV/s from the electrode with MnO<sub>2</sub> content of 45 %, followed by 195 F/gm for electrode of 67 % and 177 F/gm for electrode with 12 % respectively. However, with increasing scan rate, electrode with the highest weight and MnO<sub>2</sub> content exhibited the highest specific capacitance drop of 66 % at 100 mV/s, followed by electrodes with 45 % and 12 % MnO<sub>2</sub> at 54 % and 40% respectively. This is a common observation regarding the electrode with higher mass loading electrode. This is because at higher scan rate (faster charging/discharging rate), the ions (K<sup>+</sup>) did not penetrate the electrode pores completely, thus, giving a lower materials utilization for reduction-oxidation reaction; hence the lower specific capacitance was obtained. It also demonstrated the ability to fast charge and discharge of higher mass loading and MnO<sub>2</sub> content is poor compared to electrodes with less mass loading. One of the factors which contributes to this was the material utilization is seen to be more efficient in thin film structure, because of the shorter diffusion path of ions travelled, which effectively contributed to low resistance of the electrode. Furthermore, the specific capacitance values decrease sharply, indicating the effect of high resistivity of MnO<sub>2</sub> present in the respective electrode.

## CONCLUSION

The composite electrode of CNTs and MnO<sub>2</sub> was successfully produced through a novel method of combining electrophoretic deposition of CNTs and chemical/electrochemical deposition of metal oxides, to form a composite coating of CNTs/MnO<sub>2</sub> on the nickel current collector. This is an effective approach to produce a composite coating of CNTs- MnO<sub>2</sub> composite electrode without any binder. The role of CNTs in the composite is primarily to provide a porous template and structural network for the manganese oxide particles which will in turn provide the electrode with charge storage properties through faradaic reactions with the electrolyte. The result showed the potential of the electrodes to be used in energy storage application; especially supercapacitor.

## ACKNOWLEDGEMENT

This work was funded under Science Fund SF0095. The authors would like to offer their gratitude to MOSTI and SIRIM BERHAD for their support.
